Introduction

Paradigms of thermostatics - a subject widely known as equilibrium thermodynamics, is very different from the rest of physics. It is reasonable to classify physics into two branches. The first one is the concept of equation of motion (EoM) which can be derived from least action principle. Integrations of the postulated Lagrangian over time or spacetime (in field theory) is the action varied to obtain the Euler-Lagrange equation - the EoM, of which generalized coordinates and generalized momenta are natural dynamical variables. The other one is the concept of equation of state (EoS) in thermostatics. The EoS is constructed not theoretically like the EoM but empirically. Manifold space variables are thermodynamic coordinates such as pressure, volume, temperature, etc. without concept of time or action. We refer to the first branch as *dynamical laws*¹ and the second one as *thermostatics*².

Considering simplest hydrostatics system, mechanical intensive coordinate (Y) is the minus sign of pressure ($-P$), mechanical extensive coordinate X is volume (V), thermal intensive coordinate is temperature (T) and thermal extensive coordinate is entropy (S). Work term, $\delta W = -PdV$ is a combination of P and V , dubbed the *mechanical pair*. Heat term ($\delta Q =$

¹This includes all quantum physics, electrodynamics and gravitational theories.

²This is yet to include statistical mechanics and non-equilibrium thermodynamics into this consideration.

TdS is of the same spirit of the mechanical pair. Postulates of thermodynamics define T (in the 0th law), internal energy U (in the 1st law) and S (in the 2nd law). Constraint surface, Σ is the EoS in form of function $f(X, Y, T) = 0$, whereas $f(V, P, T) = 0$ for hydrostatics system. This 4-dimensional space (T, S, P, V) is hence constrained into 3-dimensional space (V, P, T) , (V, P, S) , (P, T, S) or (V, T, S) .

Existence of the surface Σ (the EoS), a 2-dimensional geometrical object described by 3 coordinates, enables one to define a thermodynamic potential function U according to the Carathéodory's theorem (see e.g. [1, 2]). It has been noticed that mathematics of economics equilibrium has lots of similarities to thermostatics³. Previous investigation of this analogous begins with initial setup from macroeconomics [6] or with consideration of utility function as a thermodynamics potential [7]. Here alternatively we start from the Carathéodory's axiom since, according to the axiom, the potential is to exist as the surface Σ exists. Hence in our setup, deriving EoS of an economics system, i.e. a market, is a key foundation of our paradigm.

³Although mathematical isomorphism between thermostatics and macroeconomics (neoclassical theory) was accepted by Samuelson but he did not accept that there are exact analogies of physical magnitudes in the economics realm [3]. A macroeconomic system inevitably relies on the concept of entropy and indeed economics system is driven by entropy (see e.g. [4, 5]).

Thermodynamical paradigm of economics

2.1 The zeroth law

We assume there exists a 2-dimensional Σ surface for a system which is a market, taking into account that three coordinates are quantities of demand (Q^d), supply (Q^s) and price (Pr). Price and temperature are both fundamentally postulated to exist before constructing theories of the subjects [8].

Price is defined from market equilibrium¹ as such the temperature is defined from thermal equilibrium. The zeroth law of thermodynamical paradigm of microeconomics should lay foundation of the concepts of market equilibrium and of price². The statement may read

For three efficient, perfect competitive and clearing markets A, B, C in which

¹a condition when there is no excessive demand or excessive supply

²Note that mechanism of thermal and market equilibrium formations are quite different and this is to be discussed in future work.

there are trading of the same and homogenous normal goods. If A is in equilibrium with B and B is in equilibrium with C, hence A is in equilibrium with C. The equilibrium gives rise to existence of price function which can be ranked from lower to higher and is the character of market that determines if the market is in equilibrium with others. This type of equilibrium is the price equilibrium.³

2.2 Market with Q^d and Q^s linear with price

In a market, if the demand curve is of a function (referred to standard text books e.g. [9]),

$$Q^d = k_s(Q^s) \cdot Pr + Q^{d,0}, \quad (2.1)$$

as in figure 2.1. The proportional constant is $k_s(Q^s) < 0$ and the vertical intercept is $Q^{d,0}$.

It could be elastic, unitary or inelastic demand depending on which section of the curve we consider. The supply curve is $Q^s = k_d(Q^d) \cdot Pr$ as in figure 2.1. In the same spirit with the way ideal gas law is formulated, there should be a relation $Q^d = k_{Pr}(Pr) \cdot Q^s$. Working with these relations, one finds $(Q^d)^2 = \epsilon_d^2 \cdot Pr^2 + k_d k_{Pr} \cdot Pr \cdot Q^{d,0}$ where $\epsilon_d^2 = k_d k_s k_{Pr}$ and that $(Q^s)^2 = \epsilon_s^2 \cdot Pr^2 + (k_d/k_{Pr}) \cdot Pr \cdot Q^{d,0}$ where $\epsilon_s^2 = (k_d k_s/k_{Pr})$. Point-price elasticity of demand and supply are

$$E_d = \frac{\Delta Q^d Pr_0}{\Delta Pr Q_0^d}, \quad E_s = \frac{\Delta Q^s Pr_0}{\Delta Pr Q_0^s}. \quad (2.2)$$

Since $k_s < 0$ hence ϵ_d and ϵ_s are imaginary. At market clearing price, $Q^d = Q^s$, making $k_{Pr} = 1$. The slope $\epsilon_d = \Delta Q^d / \Delta Pr = E_d Q_0^d / Pr_0 = k_s < 0$ in this case. The ϵ_d, ϵ_s hence take both imaginary and real values. The inconsistency comes from existence of vertical intercept $Q^{d,0}$ in equation (2.1) but no vertical intercept in $Q^s = k_d(Q^d) \cdot Pr$ and from that the slope k_d and k_s are forced to be equal by market clearing condition, $Q^d = Q^s$.

³There are other types of economics equilibrium such as interest rate equilibrium and exchange rate equilibrium.

รูปที่ 2.1: (a) linear price demand curve (b) linear price supply curve

2.3 Market with unitary price demand and Q^s linear with price

In distinct from Sec. 2.2, the only change is the demand function,

$$Q^d = k_s(Q^s) \cdot \frac{1}{Pr} \quad (2.3)$$

as in figure 2.2. Hence $k_s > 0$ here. Note that, $\delta Q^d = k_s \cdot \delta(Pr^{-1})$ hence slope of the hyperbolic curve is $\epsilon_d \equiv \delta Q^d / \delta Pr = -k_s / Pr^2$. Using this slope and equation (2.3) in equation (2.2) resulting $E_d = -1$ (i.e. unitary) at any points. Following similar procedure of Sec. 2.2, we find, $Q^d = \sqrt{(k_s k_{Pr} / k_d)} Q^s / Pr$. Notice that the slope of supply curve is $k_d = \epsilon_s = \Delta Q^s / \Delta Pr = E_s Q_0^s / Pr_0$. In thermostatics, the influence (mechanical force) term is an intensive variable. We shall modify the definition of Q^d to its intensive quantity that is *price demand per household*, $q^d = Q^d / N$, where N is number of household buyers. Redefining $q^d = k_s \cdot (1/Pr)$ and $q^d = k_{Pr} \cdot Q^s$, we see that k_{Pr} is a constant N^{-1} . We hence succeed in

writing $f(X, Y, T) = 0$ as

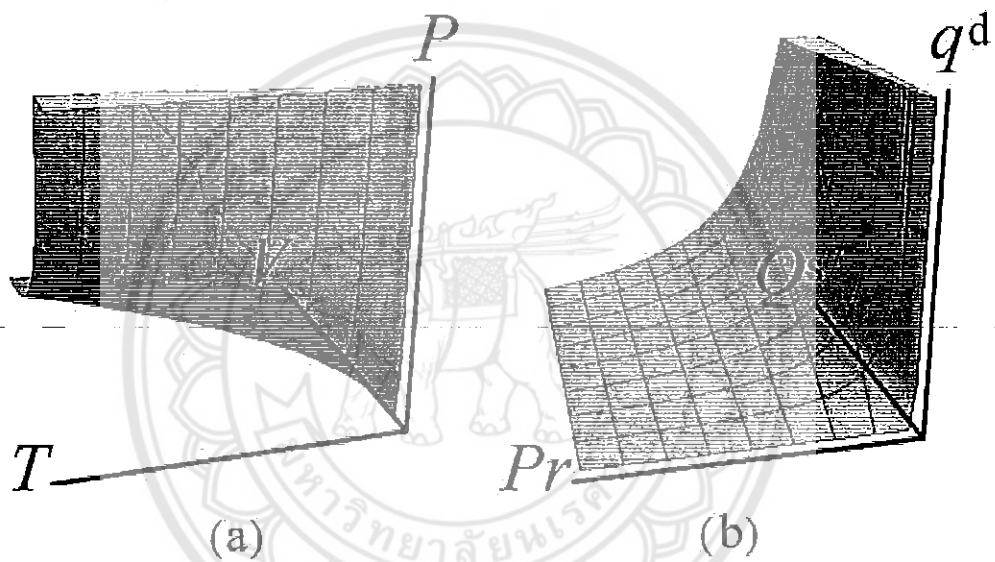

$$f(Q^s, q^d, Pr) = 0 \implies q^d = K \frac{Q^s}{Pr} \text{ or } Q^s = \frac{1}{K} q^d Pr \quad (2.4)$$

where $K \equiv \sqrt{k_s/(\varepsilon_s N)}$ playing similar role to the gas constant R or k_B combining with the specific property, e.g. compressibility factor $Z(T)$ in real virial gas. Figure 2.3 presents

analogous surface of ideal gas EoS and $f(Q^s, q^d, Pr) = 0$ as $X \equiv Q^s, Y \equiv q^d$ and $T \equiv Pr$.

รูปที่ 2.2: (a) unitary price demand: curve Q^d versus Pr is hyperbolic. The hyperbolic slope is $\varepsilon_d = \varepsilon_d(Pr)$. The curve Q^d versus $1/Pr$ is linear. Price elasticity of demand is $E_d = -1$ everywhere. (b) linear price supply curve

รูปที่ 2.3: (a) EoS of ideal gas as a 2-dim. surface (b) surface $f(Q^s, q^d, Pr) = 0$ (equation (2.4)) which could be EoS of market with unitary price elasticities of demand.

Conclusions and critics

This work attempts to find thermodynamical coordinates of a market. We propose the zeroth law such that the price plays the role of temperature. The EoS coordinates (Q^s, Q^d, P, r) are hypothesized. Market with linear price elasticity of demand is inconsistent due to market clearing (equilibrium) condition and form of equation. Inconsistency of ε comes from the need that $Q^d = Q^s$ while having two different values of slope, k_d, k_s . In case of market with unitary price elasticity of demand, it is possible to derive a constraint surface with an additional idea that the demand is considered to be intensive. Validity of this EoS is still our ongoing speculation.

We notice that as we consider equilibrium state, quantity of goods in transaction should be denoted with only one single variable, Q , not to be considered separately as two forces of willing to sell and of willing to buy. As a result, one can not draw a set of *isoprice curves* in the same spirit as isothermal curves (see figure 3.1). One of these variables might not be the correct coordinate. It is also noticed that thermal equilibrium is established in conservation condition. There are internal (the system) and external (the environment) parts to exchange heat and work hence resulting change in internal energy. The situation of market case is different.

Transactions to form clearing price in a market are done by buyers and sellers who are both internal agents. Forming an equilibrium price does not tell us the total wealth of the market while forming an equilibrium temperature does tell us how much internal energy the system possesses.

We also notice that in (P, V, T) system, P results in change of V . Both are different quantities. In simple paramagnetics, magnetic field, B_0 induces changes in magnetization \mathcal{M} , via the EoS, $\mathcal{M} = (\mathcal{D}/\mu_0)(B_0/T)$. The physical quantities B_0 and \mathcal{M} are similar in nature. Effect of B_0 is *amplified* by factor \mathcal{D} (Curie constant) to induce \mathcal{M} . In unitary market, intensive influence q^d is similar to Q^s by nature of their physical quantities. From equation (2.4), $(1/K)$ looks like the amplification factor for q^d to induce Q^s . Here we have explored possibility towards construction of an EoS for a market. We gain some insights and learn some shortcomings of the paradigm developed here to proceed in future construction of thermodynamical paradigm of economics.

รูปที่ 3.1: (a) T is an exogenous variable of the VP plane. (b) In unitary demand market, P_r is an exogenous however different prices do not give different curves but instead giving different value of $Q^s = Q^d$ via $q^d = (1/N)Q^s$. This is distinct from that of hydrostatics system where P and V are hyperbolic to each other.

Abstract. Foundations of equilibrium thermodynamics are the equation of state (EoS) and four postulated laws of thermodynamics. We use equilibrium thermodynamics paradigms in constructing the EoS for microeconomics system that is a market. This speculation is hoped to be first step towards whole pictures of thermodynamical paradigm of economics.

1. Introduction

Paradigms of thermostatics - a subject widely known as equilibrium thermodynamics, is very different from the rest of physics. It is reasonable to classify physics into two branches. The first one is the concept of equation of motion (EoM) which can be derived from least action principle. Integrations of the postulated Lagrangian over time or spacetime (in field theory) is the action varied to obtain the Euler-Lagrange equation - the EoM, of which generalized coordinates and generalized momenta are natural dynamical variables. The other one is the concept of equation of state (EoS) in thermostatics. The EoS is constructed not theoretically like the EoM but empirically. Manifold space variables are thermodynamic coordinates such as pressure, volume, temperature, etc. without concept of time or action. We refer to the first branch as *dynamical laws*¹ and the second one as *thermostatics*². Considering simplest hydrostatics system, mechanical intensive coordinate (Y) is the minus sign of pressure ($-P$), mechanical extensive coordinate X is volume (V), thermal intensive coordinate is temperature (T) and thermal extensive coordinate is entropy (S). Work term, $\delta W = -PdV$ is a combination of P and V , dubbed the *mechanical pair*. Heat term ($\delta Q = TdS$) is of the same spirit of the mechanical pair. Postulates of thermodynamics define T (in the 0th law), internal energy U (in the 1st law) and S (in the 2nd law). Constraint surface, Σ is the EoS in form of function $f(X, Y, T) = 0$, whereas $f(V, P, T) = 0$ for hydrostatics system. This 4-dimensional space (T, S, P, V) is hence constrained into 3-dimensional space (V, P, T) , (V, P, S) , (P, T, S) or (V, T, S) . Existence of the surface Σ (the EoS), a 2-dimensional geometrical object described by 3 coordinates, enables one to define a thermodynamic potential function U according to the Carathéodory's theorem

¹ This includes all quantum physics, electrodynamics and gravitational theories.

² This is yet to include statistical mechanics and non-equilibrium thermodynamics into this consideration.

(see e.g. [1, 2]). It has been noticed that mathematics of economics equilibrium has lots of similarities to thermostatics³. Previous investigation of this analogous begins with initial setup from macroeconomics [6] or with consideration of utility function as a thermodynamics potential [7]. Here alternatively we start from the Carathéodory's axiom since, according to the axiom, the potential is to exist as the surface Σ exists. Hence in our setup, deriving EoS of an economics system, i.e. a market, is a key foundation of our paradigm.

2. The zeroth law of thermodynamical paradigm of economics

We assume there exists a 2-dimensional Σ surface for a system which is a market, taking into account that three coordinates are quantities of demand (Q^d), supply (Q^s) and price (Pr). Price and temperature are both fundamentally postulated to exist before constructing theories of the subjects [8]. Price is defined from market equilibrium⁴ as such the temperature is defined from thermal equilibrium. The zeroth law of thermodynamical paradigm of microeconomics should lay foundation of the concepts of market equilibrium and of price⁵. The statement may read

For three efficient, perfect competitive and clearing markets A, B, C in which there are trading of the same and homogenous normal goods. If A is in equilibrium with B and B is in equilibrium with C, hence A is in equilibrium with C. The equilibrium gives rise to existence of price function which can be ranked from lower to higher and is the character of market that determines if the market is in equilibrium with others. This type of equilibrium is the price equilibrium.⁶

3. Market with Q^d and Q^s linear with price

In a market, if the demand curve is of a function (referred to standard text books e.g. [9]),

$$Q^d = k_s(Q^s) \cdot Pr + Q^{d,0}, \quad (1)$$

as in figure 1. The proportional constant is $k_s(Q^s) < 0$ and the vertical intercept is $Q^{d,0}$. It could be elastic, unitary or inelastic demand depending on which section of the curve we consider. The supply curve is $Q^s = k_d(Q^d) \cdot Pr$ as in figure 1. In the same spirit with the way ideal gas law is formulated, there should be a relation $Q^d = k_{Pr}(Pr) \cdot Q^s$. Working with these relations, one finds $(Q^d)^2 = \epsilon_d^2 \cdot Pr^2 + k_d k_{Pr} \cdot Pr \cdot Q^{d,0}$ where $\epsilon_d^2 = k_d k_s k_{Pr}$ and that $(Q^s)^2 = \epsilon_s^2 \cdot Pr^2 + (k_d/k_{Pr}) \cdot Pr \cdot Q^{d,0}$ where $\epsilon_s^2 = (k_d k_s/k_{Pr})$. Point-price elasticity of demand and supply are

$$E_d = \frac{\Delta Q^d}{\Delta Pr} \frac{Pr_0}{Q_0^d}, \quad E_s = \frac{\Delta Q^s}{\Delta Pr} \frac{Pr_0}{Q_0^s}. \quad (2)$$

Since $k_s < 0$ hence ϵ_d and ϵ_s are imaginary. At market clearing price, $Q^d = Q^s$, making $k_{Pr} = 1$. The slope $\epsilon_d = \Delta Q^d / \Delta Pr = E_d Q_0^d / Pr_0 = k_s < 0$ in this case. The ϵ_d, ϵ_s hence take both imaginary and real values. The inconsistency comes from existence of vertical intercept $Q^{d,0}$ in equation (1) but no vertical intercept in $Q^s = k_d(Q^d) \cdot Pr$ and from that the slope k_d and k_s are forced to be equal by market clearing condition, $Q^d = Q^s$.

³ Although mathematical isomorphism between thermostatics and macroeconomics (neoclassical theory) was accepted by Samuelson but he did not accept that there are exact analogies of physical magnitudes in the economics realm [3]. A macroeconomic system inevitably relies on the concept of entropy and indeed economics system is driven by entropy (see e.g. [4, 5]).

⁴ a condition when there is no excessive demand or excessive supply

⁵ Note that mechanism of thermal and market equilibrium formations are quite different and this is to be discussed in future work.

⁶ There are other types of economics equilibrium such as interest rate equilibrium and exchange rate equilibrium.

Figure 1. (a) linear price demand curve
(b) linear price supply curve

4. Market with unitary price demand and Q^s linear with price

In distinct from Sec. 3, the only change is the demand function,

$$Q^d = k_s(Q^s) \cdot \frac{1}{Pr}, \tag{3}$$

as in figure 2. Hence $k_s > 0$ here. Note that, $\delta Q^d = k_s \cdot \delta(Pr^{-1})$ hence slope of the hyperbolic curve is $\epsilon_d \equiv \delta Q^d / \delta Pr = -k_s / Pr^2$. Using this slope and equation (3) in equation (2) resulting $E_d = -1$ (i.e. unitary) at any points. Following similar procedure of Sec. 3, we find, $Q^d = \sqrt{(k_s k_{Pr} / k_d)} Q^s / Pr$. Notice that the slope of supply curve is $k_d = \epsilon_s = \Delta Q^s / \Delta Pr = E_s Q^s_0 / Pr_0$. In thermostatics, the influence (mechanical force) term is an intensive variable. We shall modify the definition of Q^d to its intensive quantity that is *price demand per household*, $q^d = Q^d / N$, where N is number of household buyers. Redefining $q^d = k_s \cdot (1/Pr)$ and $q^d = k_{Pr} \cdot Q^s$, we see that k_{Pr} is a constant N^{-1} . We hence succeed in writing $f(X, Y, T) = 0$ as

$$f(Q^s, q^d, Pr) = 0 \implies q^d = K \frac{Q^s}{Pr} \text{ or } Q^s = \frac{1}{K} q^d Pr \tag{4}$$

where $K \equiv \sqrt{k_s / (\epsilon_s N)}$ playing similar role to the gas constant R or k_B combining with the specific property, e.g. compressibility factor $Z(T)$ in real virial gas. Figure 3 presents analogous surface of ideal gas EoS and $f(Q^s, q^d, Pr) = 0$ as $X \equiv Q^s, Y \equiv q^d$ and $T \equiv Pr$.

Figure 2. (a) unitary price demand: curve Q^d versus Pr is hyperbolic. The hyperbolic slope is $\epsilon_d = \epsilon_d(Pr)$. The curve Q^d versus $1/Pr$ is linear. Price elasticity of demand is $E_d = -1$ everywhere.
(b) linear price supply curve

Figure 3. (a) EoS of ideal gas as a 2-dim. surface
(b) surface $f(Q^s, q^d, Pr) = 0$ (equation (4)) which could be EoS of market with unitary price elastics of demand.

5. Conclusion and critics

This work attempts to find thermodynamical coordinates of a market. We propose the zeroth law such that the price plays the role of temperature. The EoS coordinates (Q^s, Q^d, Pr) are hypothesized. Market with linear price elasticity of demand is inconsistent due to market clearing (equilibrium) condition and form of equation. Inconsistency of ϵ comes from the need that $Q^d = Q^s$ while having two different values of slope, k_d, k_s . In case of market with unitary price elasticity of demand, it is possible to derive a constraint surface with an additional idea that the demand is considered to be intensive. Validity of this EoS is still our ongoing speculation.

We notice that as we consider equilibrium state, quantity of goods in transaction should be denoted with only one single variable, Q , not to be considered separately as two forces of willing to sell and of willing to buy. ~~As a result, one can not draw a set of isoprice curves in the~~ same spirit as isothermal curves (see figure 4). One of these variables might not be the correct coordinate. It is also noticed that thermal equilibrium is established in conservation condition. There are internal (the system) and external (the environment) parts to exchange heat and work hence resulting change in internal energy. The situation of market case is different. Transactions to form clearing price in a market are done by buyers and sellers who are both internal agents. Forming an equilibrium price does not tell us the total wealth of the market while forming an equilibrium temperature does tell us how much internal energy the system possesses.

We also notice that in (P, V, T) system, P results in change of V . Both are different quantities. In simple paramagnetics, magnetic field, B_0 induces changes in magnetization M , via the EoS, $M = (D/\mu_0)(B_0/T)$. The physical quantities B_0 and M are similar in nature. Effect of B_0 is amplified by factor D (Curic constant) to induce M . In unitary market, intensive influence q^d is similar to Q^s by nature of their physical quantities. From equation (4), $(1/K)$ looks like the amplification factor for q^d to induce Q^s . Here we have explored possibility towards construction of an EoS for a market. We gain some insights and learn some shortcomings of the paradigm developed here to proceed in future construction of thermodynamical paradigm of economics.

Figure 4. (a) T is an exogenous variable of the VP plane. (b) In unitary demand market, Pr is an exogenous however different prices do not give different curves but instead giving different value of $Q^s = Q^d$ via $q^d = (1/N)Q^s$. This is distinct from that of hydrostatics system where P and V are hyperbolic to each other.
